Note: Within nine months from the publication of the mention of the grant of the European patent, any person may give notice to the European Patent Office of opposition to the European patent granted. Notice of opposition shall be filed in a written reasoned statement. It shall not be deemed to have been filed until the opposition fee has been paid (Art. 99(1) European patent convention).

## Description

This invention relates to DNA polymerases suitable for DNA sequencing and in particular relates to a method of producing the purified modified polymerases and to a purified modified gene encoding a modified DNA polymerase.

DNA sequencing involves the generation of four populations of single stranded DNA fragments having one defined terminus and one variable terminus. The variable terminus always terminates at a specific given nucleotide base (either guanine (G), adenine (A), thymine (T), or cytosine (C)). The four different sets of fragments are each separated on the basis of their length, on a high resolution polyacrylamide gel; each band on the gel corresponds colinearly to a specific nucleotide in the DNA sequence, thus identifying the positions in the sequence of the given nucleotide base.

Generally there are two methods of DNA sequencing. One method (Maxam and Gilbert sequencing) involves the chemical degradation of isolated DNA fragments, each labeled with a single radiolabel at its defined terminus, each reaction yielding a limited cleavage specifically at one or more of the four bases (G, A, T or C). The other method (dideoxy sequencing) involves the enzymatic synthesis of a DNA strand. Four separate syntheses are run, each reaction being caused to terminate at a specific base (G, A, T or C) via incorporation of the appropriate chain terminating dideoxynucleotide. The latter method is preferred since the DNA fragments are uniformly labelled (instead of end labelled) and thus the larger DNA fragments contain increasingly more radioactivity. Further, <sup>35</sup>S-labelled nucleotides can be used in place of <sup>32</sup>P-labelled nucleotides, resulting in sharper definition; and the reaction products are simple to interpret since each lane corresponds only to either G, A, T or C. The enzyme used for most dideoxy sequencing is the *Escherichia coli* DNA-polymerase I large fragment ("Klenow"). Another polymerase used is AMV reverse transcriptase.

#### Summary of the Invention

In one aspect the invention features a method for producing a purified modified DNA polymerase which method comprises expressing a modified gene which gene encodes a modified processive DNA polymerase which has sufficient DNA polymerase activity for use in DNA sequencing when said polymerase is combined with any cofactor necessary for said DNA polymerase activity and which results from the modification of a naturally occurring gene modified in that one or more amino acids in the 3' - 5' exonuclease domain of said naturally occurring DNA polymerase are replaced by an amino acid other than that naturally occurring at the site of substitution or are deleted so as to reduce the activity of naturally occurring 3' - 5' exonuclease activity of the naturally occurring DNA polymerase.

In another aspect the invention features a purified modified gene that encodes a processive modified T7-type DNA polymerase which polymerase is able to remain bound to DNA for at least 500 bases under conditions normally used for DNA sequencing reactions and which has sufficient DNA polymerase activity for use in DNA sequencing when said polymerase is combined with any host factor necessary for said DNA polymerase activity and which results from the modification of a naturally occurring gene modified to reduce the activity of naturally occurring 3' - 5' exonuclease activity of the naturally occurring DNA polymerase wherein one or more amino acids of the exonuclease domain within the amino terminal half of the T7 DNA polymerase of said naturally occurring DNA polymerase, or the corresponding domain of other T7-type DNA polymerases, are replaced by an amino acid other than that naturally occurring at the site of substitution or are deleted.

In a preferred embodiment one or more of the amino acids of the exonuclease domain from the amino terminal to amino acid residue 224 of T7 DNA polymerase of said naturally occurring DNA polymerase, or the corresponding domain of other T7-type DNA polymerases, are replaced by an amino acid other than that naturally occurring at the site of substitution or are deleted.

In preferred embodiments of the above mentioned aspects of the invention the modified polymerase encoded by the gene is able to remain bound to a DNA molecule for at least 500 bases under conditions normally used for DNA sequencing before dissociating, most preferably for at least 1,000 bases; the polymerase activity of the modified polymerase is at least 90% of that of the naturally occurring DNA polymerase; the gene encodes a modified polymerase which is substantially the same as one in cells infected with a T7-type phage (i.e., phage in which the DNA polymerase requires host thioredoxin as a subunit) for example, the T7-type phage is T7, T3,  $\phi$ I,  $\phi$ II, H, W31, gh-I, Y, AII22, or Sp6; the polymerase is non-discriminating for dideoxy nucleotide analogs; the polymerase has a 3' - 5' exonuclease activity at least 50% lower than the naturally-occurring exonuclease activity of naturally occurring T7-type DNA polymerase; the polymerase is modified to reduce the activity of the naturally occurring 3' - 5' exonuclease activity to

less than 500 units per mg of polymerase, more preferably less than 1 unit, even more preferably less than 0.1 unit, and most preferably has no detectable exonuclease activity; the polymerase is able to utilize primers of as short as 10 bases or preferably as short as 4 bases; the primer comprises four to forty nucleotide bases, and is single stranded DNA or RNA. Preferably the modified gene encodes a modified DNA polymerase in which a naturally occurring His residue of the naturally occurring DNA polymerase is replaced or deleted. In embodiments described herein after His 123, Ser 122 and His 123, Lys 118 to His 123, Lys 118 and Arg 119 or Arg 131, Lys 136, Lys 140, Lys 144 and Arg 145 of the naturally occurring T7 DNA Polymerase are replaced or deleted.

This invention provides a DNA polymerase which is processive, non-discriminating, and can utilize short primers. Further, the polymerase has no associated exonuclease activity. These are ideal properties for the above described methods, and in particular for DNA sequencing reactions, since the background level of radioactivity in the polyacrylamide gels is negligible, there are few or no artifactual bands, and the bands are sharp -- making the DNA sequence easy to read. Further, such a polymerase allows novel methods of sequencing long DNA fragments, as is described in detail below.

Other features and advantages of the invention will be apparent from the following description of the preferred embodiments thereof and from the claims.

#### Description of the Preferred Embodiments

The drawings will first briefly be described.

#### Drawings

Figs. 1-3 are diagrammatic representations of the vectors pTrx-2, mGP1-1, and pGP5-5 respectively; Fig. 4 is a graphical representation of the selective oxidation of T7 DNA polymerase; Fig. 5 is a graphical representation of the ability of modified T7 polymerase to synthesize DNA in the presence of etheno-dATP; and Fig. 6 is a diagrammatic representation of the enzymatic amplification of genomic DNA using modified T7 DNA polymerase. Fig. 7, 8 and 9 are the nucleotide sequences of pTrx-2, a part of pGP5-5 and mGP1-2 respectively. Fig. 10 is a diagrammatic representation of pGP5-6.

#### DNA Polymerase

In general the DNA polymerase of this invention is processive, has no associated exonuclease activity, does not discriminate against nucleotide analog incorporation, and can utilize small oligonucleotides (such as tetramers, hexamers and octamers) as specific primers. These properties will now be discussed in detail.

#### Processivity

By processivity is meant that the DNA polymerase is able to continuously incorporate many nucleotides using the same primer-template without dissociating from the template, under conditions normally used for DNA sequencing extension reactions. The degree of processivity varies with different polymerases: some incorporate only a few bases before dissociating (e.g. Klenow (about 15 bases), T4 DNA polymerase (about 10 bases), T5 DNA polymerase (about 180 bases) and reverse transcriptase (about 200 bases) (Das et al. J. Biol. Chem. 254:1227 1979; Bambara et al., J. Biol. Chem. 253:413, 1978) while others, such as those of the present invention, will remain bound for at least 500 bases and preferably at least 1,000 bases under suitable environmental conditions. Such environmental conditions include having adequate supplies of all four deoxynucleoside triphosphates and an incubation temperature from 10°C-50°C. Processivity is greatly enhanced in the presence of *E. coli* single stranded binding (ssb), protein.

With processive enzymes termination of a sequencing reaction will occur only at those bases which have incorporated a chain terminating agent, such as a dideoxynucleotide. If the DNA polymerase is non-processive, then artifactual bands will arise during sequencing reactions, at positions corresponding to the nucleotide where the polymerase dissociated. Frequent dissociation creates a background of bands at incorrect positions and obscures the true DNA sequence. This problem is partially corrected by incubating the reaction mixture for a long time (30-60 min) with a high concentration of substrates, which "chase" the artifactual bands up to a high molecular weight at the top of the gel, away from the region where the DNA sequence is read. This is not an ideal solution since a non-processive DNA polymerase has a high

probability of dissociating from the template at regions of compact secondary structure, or hairpins. Reinitiation of primer elongation at these sites is inefficient and the usual result is the formation of bands at the same position for all four nucleotides, thus obscuring the DNA sequence.

#### 5 Analog discrimination

The DNA polymerases of this invention do not discriminate significantly between dideoxy-nucleotide analogs and normal nucleotides. That is, the chance of incorporation of an analog is approximately the same as that of a normal nucleotide or at least incorporates the analog with at least 1/10 the efficiency that  
 10 of a normal analog. The polymerases of this invention also do not discriminate significantly against some other analogs. This is important since, in addition to the four normal deoxynucleoside triphosphates (dGTP, dATP, dTTP and dCTP), sequencing reactions require the incorporation of other types of nucleotide derivatives such as: radioactively-or fluorescently-labelled nucleoside triphosphates, usually for labeling the synthesized strands with  $^{35}\text{S}$ ,  $^{32}\text{P}$ , or other chemical agents. When a DNA polymerase does not discriminate  
 15 against analogs the same probability will exist for the incorporation of an analog as for a normal nucleotide. For labelled nucleoside triphosphates this is important in order to efficiently label the synthesized DNA strands using a minimum of radioactivity. Further, lower levels of analogs are required with such enzymes, making the sequencing reaction cheaper than with a discriminating enzyme.

Discriminating polymerases show a different extent of discrimination when they are polymerizing in a  
 20 processive mode versus when stalled, struggling to synthesize through a secondary structure impediment. At such impediments there will be a variability in the intensity of different radioactive bands on the gel, which may obscure the sequence.

#### Exonuclease Activity

25 The DNA polymerase of the invention has less than 50%, preferably less than 1%, and most preferably less than 0.1%, of the normal or naturally associated level of exonuclease activity (amount of activity per polymerase molecule). By normal or naturally associated level is meant the exonuclease activity of unmodified T7-type polymerase. Normally the associated activity is about 5,000 units of exonuclease  
 30 activity per mg of polymerase, measured as described below by a modification of the procedure of Chase et al. (249 J. Biol. Chem. 4545, 1974). Exonucleases increase the fidelity of DNA synthesis by excising any newly synthesized bases which are incorrectly basepaired to the template. Such associated exonuclease activities are detrimental to the quality of DNA sequencing reactions. They raise the minimal required concentration of nucleotide precursors which must be added to the reaction since, when the nucleotide  
 35 concentration falls, the polymerase activity slows to a rate comparable with the exonuclease activity, resulting in no net DNA synthesis, or even degradation of the synthesized DNA.

More importantly, associated exonuclease activity will cause a DNA polymerase to idle at regions in the template with secondary structure impediments. When a polymerase approaches such a structure its rate of synthesis decreases as it struggles to pass. An associated exonuclease will excise the newly synthesized  
 40 DNA when the polymerase stalls. As a consequence numerous cycles of synthesis and excision will occur. This may result in the polymerase eventually synthesizing past the hairpin (with no detriment to the quality of the sequencing reaction); or the polymerase may dissociate from the synthesized strand (resulting in an artifactual band at the same position in all four sequencing reactions); or, a chain terminating agent may be incorporated at a high frequency and produce a wide variability in the intensity of different fragments in a  
 45 sequencing gel. This happens because the frequency of incorporation of a chain terminating agent at any given site increases with the number of opportunities the polymerase has to incorporate the chain terminating nucleotide, and so the DNA polymerase will incorporate a chain-terminating agent at a much higher frequency at sites of idling than at other sites.

An ideal sequencing reaction will produce bands of uniform intensity throughout the gel. This is  
 50 essential for obtaining the optimal exposure of the X-ray film for every radioactive fragment. If there is variable intensity of radioactive bands, then fainter bands have a chance of going undetected. To obtain uniform radioactive intensity of all fragments, the DNA polymerase should spend the same interval of time at each position on the DNA, showing no preference for either the addition or removal of nucleotides at any given site. This occurs if the DNA polymerase lacks any associated exonuclease, so that it will have only  
 55 one opportunity to incorporate a chain terminating nucleotide at each position along the template.

Short primers

The DNA polymerase of the invention is able to utilize primers of 10 bases or less, as well as longer ones, most preferably of 4-20 bases. The ability to utilize short primers offers a number of important advantages to DNA sequencing. The shorter primers are cheaper to buy and easier to synthesize than the usual 15-20-mer primers. They also anneal faster to complementary sites on a DNA template, thus making the sequencing reaction faster. Further, the ability to utilize small (e.g., six or seven base) oligonucleotide primers for DNA sequencing permits strategies not otherwise possible for sequencing long DNA fragments. For example, a kit containing 80 random hexamers could be generated, none of which are complementary to any sites in the cloning vector. Statistically, one of the 80 hexamer sequences will occur an average of every 50 bases along the DNA fragment to be sequenced. The determination of a sequence of 3000 bases would require only five sequencing cycles. First, a "universal" primer (e.g., New England Biolabs #1211, sequence 5' GTAAAACGACGGCCAGT 3') would be used to sequence about 600 bases at one end of the insert. Using the results from this sequencing reaction, a new primer would be picked from the kit homologous to a region near the end of the determined sequence. In the second cycle, the sequence of the next 600 bases would be determined using this primer. Repetition of this process five times would determine the complete sequence of the 3000 bases, without necessitating any subcloning, and without the chemical synthesis of any new oligonucleotide primers. The use of such short primers may be enhanced by including gene 2.5 and 4 protein of T7 in the sequencing reaction.

DNA polymerases of this invention, (i.e., having the above properties) include modified T7-type polymerases. That is the DNA polymerase requires host thioredoxin as a sub-unit, and they are substantially identical to a modified T7 DNA polymerase or to equivalent enzymes isolated from related phage, such as T3,  $\phi$ I,  $\phi$ II, H, W31, gh-1, Y, A1122 and SP6. Each of these enzymes can be modified to have properties similar to those of the modified T7 enzyme. It is possible to isolate the enzyme from phage infected cells directly, but preferably the enzyme is isolated from cells which overproduce it. By substantially identical is meant that the enzyme may have amino acid substitutions which do not affect the overall properties of the enzyme. One example of a particularly desirable amino acid substitution is one in which the natural enzyme is modified to remove any exonuclease activity. This modification may be performed at the genetic or chemical level (see below).

Cloning T7 polymerase

As an example of the invention we shall describe the cloning, overproduction, purification, modification and use of T7 DNA polymerase. This processive enzyme consists of two polypeptides tightly complexed in a one to one stoichiometry. One is the phage T7-encoded gene 5 protein of 84,000 daltons (Modrich et al. 150 J. Biol. Chem. 5515, 1975), the other is the *E. coli* encoded thioredoxin, of 12,000 daltons (Tabor et al., J. Biol. Chem. 262:16, 216, 1987). The thioredoxin is an accessory protein and attaches the gene 5 protein (the non-processive actual DNA polymerase) to the primer template. The natural DNA polymerase has a very active 3' to 5' exonuclease associated with it. This activity makes the polymerase useless for DNA sequencing and must be inactivated or modified before the polymerase can be used. This is readily performed, as described below, either chemically, by local oxidation of the exonuclease domain, or genetically, by modifying the coding region of the polymerase gene encoding this activity.

pTrx-2

In order to clone the *trxA* (thioredoxin) gene of *E. coli* wild type *E. coli* DNA was partially cleaved with *Sau*3A and the fragments ligated to *Bam*HI-cleaved T7 DNA isolated from strain T7 ST9 (Tabor et al., in *Thioredoxin and Glutaredoxin Systems: Structure and Function* (Holmgren et al., eds) pp. 285-300, Raven Press, NY; and Tabor et al., *supra*). The ligated DNA was transfected into *E. coli trxA*<sup>-</sup> cells, the mixture plated onto *trxA*<sup>-</sup> cells, and the resulting T7 plaques picked. Since T7 cannot grow without an active *E. coli trxA* gene only those phages containing the *trxA* gene could form plaques. The cloned *trxA* genes were located on a 470 base pair *Hinc*II fragment.

In order to overproduce thioredoxin a plasmid, pTrx-2, was as constructed. Briefly, the 470 base pair *Hinc*II fragment containing the *trxA* gene was isolated by standard procedure (Maniatis et al., *Cloning: A Laboratory Manual*, Cold Spring Harbor Labs., Cold Spring Harbor, N.Y.), and ligated to a derivative of pBR322 containing a *Ptac* promoter (*ptac*-12, Amann et al., 25 Gene 167, 1983). Referring to Fig. 2, *ptac*-12, containing  $\beta$ -lactamase and *Col* EI origin, was cut with *Pvu*II, to yield a fragment of 2290 bp, which was then ligated to two tandem copies of *trxA* (*Hinc*II fragment) using commercially available linkers (*Sma*-

BamHI polylinker), to form pTrx-2. The complete nucleotide sequence of pTrx-2 is shown in Figure 7. Thioredoxin production is now under the control of the tac promoter, and thus can be specifically induced, e.g. by IPTG (isopropyl  $\beta$ -D-thiogalactoside).

#### 5 pGP5-5 and mGP1-2

Some gene products of T7 are lethal when expressed in *E. coli*. An expression system was developed to facilitate cloning and expression of, lethal genes, based on the inducible expression of T7 RNA polymerase. Gene 5 protein is lethal in some *E. coli* strains and an example of such a system is described by Tabor et al. 82 Proc. Nat. Acad. Sci. 1074 (1985) where T7 gene 5 was placed under the control of the  $\phi$ 10 promoter, and is only expressed when T7 RNA polymerase is present in the cell.

Briefly, pGP5-5 (Fig. 3) was constructed by standard procedures using synthetic BamHI linkers to join T7 fragment from 14306 (NdeI) to 16869 (AhaIII), containing gene 5, to the 560 bp fragment of T7 from 5667 (HincII) to 6166 (Fnu4H1) containing both the  $\phi$ 1.1A and  $\phi$ 1.1B promoters, which are recognized by T7 RNA polymerase, and the 3kb BamHI-HincII fragment of pACYC177 (Chang et al., 134 J. Bacteriol. 1141, 1978). The nucleotide sequence of the T7 inserts and linkers is shown in Fig. 8. In this plasmid gene 5 is only expressed when T7 RNA polymerase is provided in the cell.

Referring to Fig. 3, T7 RNA polymerase is provided on phage vector mGP1-2. This is similar to pGP1-2 (Tabor et al., *id.*) except that the fragment of T7 from 3133 (HaeIII) to 5840 (Hinfl), containing T7 RNA polymerase was ligated, using linkers (BglII and SalI respectively), to BamHI-SalI cut M13 mp8, placing the polymerase gene under control of the lac promoter. The complete nucleotide sequence of mGP1-2 is shown in Fig. 9.

Since pGP5-5 and pTrx-2 have different origins of replication (respectively a P15A and a ColE1 origin) they can be transformed into one cell simultaneously. pTrx-2 expresses large quantities of thioredoxin in the presence of IPTG. mGP1-2 can coexist in the same cell as these two plasmids and be used to regulate expression of T7-DNA polymerase from pGP5-5, simply by causing production of T7-RNA polymerase by inducing the lac promoter with, e.g., IPTG.

#### 30 Overproduction of T7 DNA polymerase

There are several potential strategies for overproducing and reconstituting the two gene products of trxA and gene 5. The same cell strains and plasmids can be utilized for all the strategies. In the preferred strategy the two genes are co-overexpressed in the same cell. (This is because gene 5 is susceptible to proteases until thioredoxin is bound to it.) As described in detail below, one procedure is to place the two genes separately on each of two compatible plasmids in the same cell. Alternatively, the two genes could be placed in tandem on the same plasmid. It is important that the T7-gene 5 is placed under the control of a non-leaky inducible promoter, such as  $\phi$ 1.1A,  $\phi$ 1.1B and  $\phi$ 10 of T7, as the synthesis of even small quantities of the two polypeptides together is toxic in most *E. coli* cells. By non-leaky is meant that less than 500 molecules of the gene product are produced, per cell generation time, from the gene when the promoter, controlling the gene's expression, is not activated. Preferably the T7 RNA polymerase expression system is used although other expression systems which utilize inducible promoters could also be used. A leaky promoter, e.g., plac, allows more than 500 molecules of protein to be synthesized, even when not induced, thus cells containing lethal genes under the control of such a promoter grow poorly and are not suitable in this invention. It is of course possible to produce these products in cells where they are not lethal, for example, the plac promoter is suitable in such cells.

In a second strategy each gene can be cloned and overexpressed separately. Using this strategy, the cells containing the individually overproduced polypeptides are combined prior to preparing the extracts, at which point the two polypeptides form an active T7 DNA polymerase.

#### 50 Example 1: Production of T7 DNA polymerase

*E. coli* strain 71.18 (Messing et al., Proc. Nat. Acad. Sci. 74:3642, 1977) is used for preparing stocks of mGP1-2. 71.18 is stored in 50% glycerol at -80°C. and is streaked on a standard minimal media agar plate. A single colony is grown overnight in 25 ml standard M9 media at 37°C, and a single plaque of mGP1-2 is obtained by titrating the stock using freshly prepared 71.18 cells. The plaque is used to inoculate 10 ml 2X LB (2% Bacto-Tryptone, 1% yeast extract, 0.5% NaCl, 8mM NaOH) containing JM103 grown to an  $A_{590}$  = 0.5. This culture will provide the phage stock for preparing a large culture of mGP1-2. After 3-12 hours, the 10 ml culture is centrifuged, and the supernatant used to infect the large (2L) culture. For the

large culture, 4 X 500 ml 2X LB is inoculated with 4 X 5 ml 71.18 cells grown in M9, and is shaken at 37°C. When the large culture of cells has grown to an  $A_{590} = 1.0$  (approximately three hours), they are inoculated with 10 ml of supernatant containing the starter lysate of mGP1-2. The infected cells are then grown overnight at 37°C. The next day, the cells are removed by centrifugation, and the supernatant is ready to use for induction of K38/pGP5-5/pTrx-2 (see below). The supernatant can be stored at 4°C for approximately six months, at a titer  $\sim 5 \times 10^{11}$   $\phi$ /ml. At this titer, 1 L of phage will infect 12 liters of cells at an  $A_{590} = 5$  with a multiplicity of infection of 15. If the titer is low, the mGP1-2 phage can be concentrated from the supernatant by dissolving NaCl (60 gm/liter) and PEG-6000 (65 gm/liter) in the supernatant, allowing the mixture to settle at 0°C for 1-72 hours, and then centrifuging (7000 rpm for 20 min). The precipitate, which contains the mGP1-2 phage, is resuspended in approximately 1/20th of the original volume of M9 media.

K38/pGP5-5/pTrx-2 is the *E. coli* strain (genotype HfrC ( $\lambda$ )) containing the two compatible plasmids pGP5-5 and pTrx-2. pGP5-5 plasmid has a P15A origin of replication and expresses the kanamycin (Km) resistance gene. pTrx-2 has a ColEI origin of replication and expresses the ampicillin (Ap) resistance gene. The plasmids are introduced into K38 by standard procedures, selecting Km<sup>R</sup> and Ap<sup>R</sup> respectively. The cells K38/pGP5-5/pTrx-2 are stored in 50% glycerol at -80°C. Prior to use they are streaked on a plate containing 50  $\mu$ g/ml ampicillin and kanamycin, grown at 37°C overnight, and a single colony grown in 10 ml LB media containing 50  $\mu$ g/ml ampicillin and kanamycin, at 37°C for 4-6 hours. The 10 ml cell culture is used to inoculate 500 ml of LB media containing 50  $\mu$ g/ml ampicillin and kanamycin and shaken at 37°C overnight. The following day, the 500 ml culture is used to inoculate 12 liters of 2X LB-KPO<sub>4</sub> media (2% Bacto-Tryptone, 1% yeast extract, 0.5% NaCl, 20 mM KPO<sub>4</sub>, 0.2% dextrose, and 0.2% casamino acids, pH 7.4), and grown with aeration in a fermentor at 37°C. When the cells reach an  $A_{590} = 5.0$  (i.e. logarithmic or stationary phase cells), they are infected with mGP1-2 at a multiplicity of infection of 10, and IPTG is added (final concentration 0.5mM). The IPTG induces production of thioredoxin and the T7 RNA polymerase in mGP1-2, and thence induces production of the cloned DNA polymerase. The cells are grown for an additional 2.5 hours with stirring and aeration, and then harvested. The cell pellet is resuspended in 1.5 L 10% sucrose/20 mM Tris-HCl, pH 8.0/25 mM EDTA and re-spun. Finally, the cell pellet is resuspended in 200 ml 10% sucrose/20 mM Tris-HCl, pH 8/1.0 mM EDTA, and frozen in liquid N<sub>2</sub>. From 12 liters of induced cells 70 gm of cell paste are obtained containing approximately 700 mg gene 5 protein and 100 mg thioredoxin.

K38/pTrx-2 (K38 containing pTrx-2 alone) overproduces thioredoxin, and it is added as a "booster" to extracts of K38/pGP5-5/pTrx-2 to insure that thioredoxin is in excess over gene 5 protein at the outset of the purification. The K38/pTrx-2 cells are stored in 50% glycerol at -80°C. Prior to use they are streaked on a plate containing 50  $\mu$ g/ml ampicillin, grown at 37°C for 24 hours, and a single colony grown at 37°C overnight in 25 ml LB media containing 50  $\mu$ g/ml ampicillin. The 25 ml culture is used to inoculate 2 L of 2X LB media and shaken at 37°C. When the cells reach an  $A_{590} = 3.0$ , the ptac promoter, and thus thioredoxin production, is induced by the addition of IPTG (final concentration 0.5 mM). The cells are grown with shaking for an additional 12-16 hours at 37°C, harvested, resuspended in 600 ml 10% sucrose/20 mM Tris-HCl, pH 8.0/25 mM EDTA, and re-spun. Finally, the cells are resuspended in 40 ml 10% sucrose/20 mM Tris-HCl, pH 8/0.5 mM EDTA, and frozen in liquid N<sub>2</sub>. From 2L of cells 16 gm of cell paste are obtained containing 150 mg of thioredoxin.

Assays for the polymerase involve the use of single-stranded calf thymus DNA (6mM) as a substrate. This is prepared immediately prior to use by denaturation of double-stranded calf thymus DNA with 50 mM NaOH at 20°C for 15 min., followed by neutralization with HCl. Any purified DNA can be used as a template for the polymerase assay, although preferably it will have a length greater than 1,000 bases.

The standard T7 DNA polymerase assay used is a modification of the procedure described by Grippo et al. (246 J. Biol. Chem. 6867, 1971). The standard reaction mix (200  $\mu$ l final volume) contains 40 mM Tris/HCl pH 7.5, 10 mM MgCl<sub>2</sub>, 5 mM dithiothreitol, 100 nmol alkali-denatured calf thymus DNA, 0.3 dGTP, dATP, dCTP and [<sup>3</sup>H]dTTP (20 cpm/pmol), 50  $\mu$ g/ml BSA, and varying amounts of T7 DNA polymerase. Incubation is at 37°C (10°C-45°C) for 30 min (5 min-60 min). The reaction is stopped by the addition of 3 ml of cold (0°C) 1 N HCl-0.1 M pyrophosphate. Acid-insoluble radioactivity is determined by the procedure of Hinkle et al. (250 J. Biol. Chem. 5523, 1974). The DNA is precipitated on ice for 15 min (5 min-12 hr), then precipitated onto glass-fiber filters by filtration. The filters are washed five times with 4 ml of cold (0°C) 0.1M HCl-0.1M pyrophosphate, and twice with cold (0°C) 90% ethanol. After drying, the radioactivity on the filters is counted using a non-aqueous scintillation fluor.

One unit of polymerase activity catalyzes the incorporation of 10 nmol of total nucleotide into an acid-soluble form in 30 min at 37°C, under the conditions given above. Native T7 DNA polymerase and modified T7 DNA polymerase (see below) have the same specific polymerase activity  $\pm$  20%, which ranges between 5,000-20,000 units/mg for native and 5,000-50,000 units/mg for modified polymerase) depending upon the

preparation, using the standard assay conditions stated above.

T7 DNA polymerase is purified from the above extracts by precipitation and chromatography techniques. An example of such a purification follows.

An extract of frozen cells (200 ml K38/pGP5-5/pTrx-2 and 40 ml K38/pTrx-2) are thawed at 0°C overnight. The cells are combined, and 5 ml of lysozyme (15 mg/ml) and 10 ml of NaCl (5M) are added. After 45 min at 0°C, the cells are placed in a 37°C water bath until their temperature reaches 20°C. The cells are then frozen in liquid N<sub>2</sub>. An additional 50 ml of NaCl (5M) is added, and the cells are thawed in a 37°C water bath. After thawing, the cells are gently mixed at 0°C for 60 min. The lysate is centrifuged for one hr at 35,000 rpm in a Beckman 45Ti rotor. The supernatant (250 ml) is fraction I. It contains approximately 700 mg gene 5 protein and 250 mg of thioredoxin (a 2:1 ratio thioredoxin to gene 5 protein).

90 gm of ammonium sulphate is dissolved in fraction I (250 ml) and stirred for 60 min. The suspension is allowed to sit for 60 min, and the resulting precipitate collected by centrifugation at 8000 rpm for 60 min. The precipitate is redissolved in 300 ml of 20 mM Tris-HCl pH 7.5/5 mM 2-mercaptoethanol/0.1 mM EDTA/10% glycerol (Buffer A). This is fraction II.

A column of Whatman DE52 DEAE (12.6 cm<sup>2</sup> x 18 cm) is prepared and washed with Buffer A. Fraction II is dialyzed overnight against two changes of 1 L of Buffer A each until the conductivity of Fraction II has a conductivity equal to that of Buffer A containing 100 mM NaCl. Dialyzed Fraction II is applied to the column at a flow rate of 100 ml/hr, and washed with 400 ml of Buffer A containing 100 NaCl. Proteins are eluted with a 3.5 L gradient from 100 to 400 mM NaCl in Buffer A at a flow rate of 60 ml/hr. Fractions containing T7 DNA polymerase, which elutes at 200 mM NaCl, are pooled. This is fraction III (190 ml).

A column of Whatman P11 phosphocellulose (12.6 cm<sup>2</sup> x 11 cm) is prepared and washed with 20 mM KPO<sub>4</sub> pH 7.4/5 mM 2-mercaptoethanol/0.1 mM EDTA/10 % glycerol (Buffer B). Fraction III is diluted 2-fold (380 ml) with Buffer B, then applied to the column at a flow rate of 60 ml/hr and washed with 200 ml of Buffer B containing 100mM KCl. Proteins are eluted with a 1.8 L gradient from 100 to 400 mM KCl in Buffer B at a flow rate of 60 ml/hr. Fractions containing T7 DNA polymerase which elutes at 300 KCl, are pooled. This is fraction IV (370 ml).

A column of DEAE-Sephadex A-50 (4.9 cm<sup>2</sup> x 15 cm) is prepared and washed with 20 mM Tris-HCl 7.0/0.1 mM dithiothreitol/0.1 mM EDTA/10% glycerol (Buffer C). Fraction IV is dialyzed against two changes of 1 L Buffer C to a final conductivity equal to that of Buffer C containing 100 mM NaCl. Dialyzed fraction IV is applied to the column at a flow rate of 40 ml/hr, and washed with 150 ml of Buffer C containing 100 mM NaCl. Proteins are eluted with a 1 L gradient from 100 to 300 mM NaCl in Buffer C at a flow rate of 40 ml/hr. Fractions containing T7 DNA polymerase, which elutes at 210 mM NaCl, are pooled. This is fraction V (120 ml).

A column of BioRad HTP hydroxylapatite (4.9 cm<sup>2</sup> x 15 cm) is prepared and washed with 20 mM KPO<sub>4</sub>, pH 7.4/10 mM 2-mercaptoethanol/2 mM Na citrate/10% glycerol (Buffer D). Fraction V is dialyzed against two changes of 500 ml Buffer D each. Dialyzed fraction V is applied to the column at a flow rate of 30 ml/hr, and washed with 100 ml of Buffer D. Proteins are eluted with a 900 ml gradient from 0 to 180 mM KPO<sub>4</sub>, pH 7.4 in Buffer D at a flow rate of 30 ml/hr. Fractions containing T7 DNA polymerases which elutes at 50 mM KPO<sub>4</sub>, are pooled. This is fraction VI (130 ml). It contains 270 mg of homogeneous T7 DNA polymerase.

Fraction VI is dialyzed versus 20 mM KPO<sub>4</sub> pH 7.4/0.1 mM dithiothreitol/0.1 mM EDTA/50% glycerol. This is concentrated fraction VI (~65 ml, 4 mg/ml), and is stored at -20°C.

The isolated T7 polymerase has exonuclease activity associated with it. As stated above this must be inactivated. An example of inactivation by chemical modification follows.

Concentrated fraction VI is dialyzed overnight against 20 mM KPO<sub>4</sub> pH 7.4/0.1 mM dithiothreitol/10% glycerol to remove the EDTA present in the storage buffer. After dialysis, the concentration is adjusted to 2 mg/ml with 20 mM KPO<sub>4</sub> pH 7.4/0.1 mM dithiothreitol/10% glycerol, and 30 ml (2mg/ml) aliquots are placed in 50 ml polypropylene tubes. (At 2 mg/ml, the molar concentration of T7 DNA polymerase is 22 μM.)

Dithiothreitol (DTT) and ferrous ammonium sulfate (Fe(NH<sub>4</sub>)<sub>2</sub>(SO<sub>4</sub>)<sub>2</sub>·6H<sub>2</sub>O) are prepared fresh immediately before use, and added to a 30 ml aliquot of T7 DNA polymerase, to concentrations of 5 mM DTT (0.6 ml of a 250 stock) and 20μM Fe(NH<sub>4</sub>)<sub>2</sub>(SO<sub>4</sub>)<sub>2</sub>·6H<sub>2</sub>O (0.6 ml of a 1 mM stock). During modification the molar concentrations of T7 DNA polymerase and iron are each approximately 20 μM, while DTT is in 250X molar excess.

The modification is carried out at 0°C under a saturated oxygen atmosphere as follows. The reaction mixture is placed on ice within a dessicator, the dessicator is purged of air by evacuation and subsequently filled with 100% oxygen. This cycle is repeated three times. The reaction can be performed in air (20% oxygen), but occurs at one third the rate.

The time course of loss of exonuclease activity is shown in Fig. 4.  $^3\text{H}$ -labeled double-stranded DNA (6 cpm/pmol) was prepared from bacteriophage T7 as described by Richardson (15 J. Molec. Biol. 49, 1966).  $^3\text{H}$ -labeled single-stranded T7 DNA was prepared immediately prior to use by denaturation of double-stranded  $^3\text{H}$ -labeled T7 DNA with 50 mM NaOH at 20°C for 15 min, followed by neutralization with HCl.

5 The standard exonuclease assay used is a modification of the procedure described by Chase et al. (*supra*). The standard reaction mixture (100  $\mu\text{l}$  final volume) contained 40 mM Tris/HCl pH 7.5, 10 mM  $\text{MgCl}_2$ , 10 mM dithiothreitol, 60 nmol  $^3\text{H}$ -labeled single-stranded T7 DNA (6 cpm/pm), and varying amounts of T7 DNA polymerase.  $^3\text{H}$ -labeled double-stranded T7 DNA can also be used as a substrate. Also, any uniformly radioactively labeled DNA, single- or double-stranded, can be used for the assay. Also, 3' end labeled

10 single- or double-stranded DNA can be used for the assay. After incubation at 37°C for 15 min, the reaction is stopped by the addition of 30  $\mu\text{l}$  of BSA (10mg/ml) and 25  $\mu\text{l}$  of TCA (100% w/v). The assay can be run at 10°C-45°C for 1-60 min. The DNA is precipitated on ice for 15 min (1 min - 12 hr), then centrifuged at 12,000 g for 30 min (5 min - 3 hr). 100  $\mu\text{l}$  of the supernatant is used to determine the acid-soluble radioactivity by adding it to 400  $\mu\text{l}$  water and 5 ml of aqueous scintillation cocktail.

15 One unit of exonuclease activity catalyzes the acid solubilization of 10 nmol of total nucleotide in 30 min under the conditions of the assay. Native T7 DNA polymerase has a specific exonuclease activity of 5000 units/mg, using the standard assay conditions stated above. The specific exonuclease activity of the modified T7 DNA polymerase depends upon the extent of chemical modification, but ideally is at least 10-100-fold lower than that of native T7 DNA polymerase, or 500 to 50 or less units/mg using the standard

20 assay conditions stated above. When double stranded substrate is used the exonuclease activity is about 7-fold higher.

Under the conditions outlined, the exonuclease activity decays exponentially, with a half-life of decay of eight hours. Once per day the reaction vessel is mixed to distribute the soluble oxygen, otherwise the reaction will proceed more rapidly at the surface where the concentration of oxygen is higher. Once per day

25 2.5 mM DTT (0.3 ml of a fresh 250 mM stock to a 30 ml reaction) is added to replenish the oxidized DTT.

After eight hours, the exonuclease activity of T7 DNA polymerase has been reduced 50%, with negligible loss of polymerase activity. The 50% loss may be the result of the complete inactivation of exonuclease activity of half the polymerase molecules, rather than a general reduction of the rate of exonuclease activity in all the molecules. Thus, after an eight hour reaction all the molecules have normal

30 polymerase activity, half the molecules have normal exonuclease activity, while the other half have <0.1% of their original exonuclease activity.

When 50% of the molecules are modified (an eight hour reaction), the enzyme is suitable, although suboptimal, for DNA sequencing. For more optimum quality of DNA sequencing, the reaction is allowed to proceed to greater than 99% modification (having less than 50 units of exonuclease activity), which requires

35 four days.

After four days, the reaction mixture is dialyzed against 2 changes of 250 ml of 20 mM  $\text{KPO}_4$  pH 7.4/0.1 mM dithiothreitol/0.1 mM EDTA/50% glycerol to remove the iron. The modified T7 DNA polymerase (~4 mg/ml) is stored at -20°C.

The reaction mechanism for chemical modification of T7 DNA polymerase depends upon reactive

40 oxygen species generated by the presence of reduced transition metals such as  $\text{Fe}^{2+}$  and oxygen. A possible reaction mechanism for the generation of hydroxyl radicals is outlined below:

In equation 1, oxidation of the reduced metal ion yields superoxide radical,  $\text{O}_2^{\cdot -}$ . The superoxide radical

50 can undergo a dismutation reaction, producing hydrogen peroxide (equation 2). Finally, hydrogen peroxide can react with reduced metal ions to form hydroxyl radicals,  $\text{OH}^{\cdot}$  (the Fenton reaction, equation 3). The oxidized metal ion is recycled to the reduced form by reducing agents such as dithiothreitol (DTT).

These reactive oxygen species probably inactivate proteins by irreversibly chemically altering specific amino acid residues. Such damage is observed in SDS-PAGE of fragments of gene 5 produced by CNBr or

55 trypsin. Some fragments disappear, high molecular weight cross linking occurs, and some fragments are broken into two smaller fragments.

As previously mentioned, oxygen, a reducing agent (e.g. DTT, 2-mercaptoethanol) and a transition metal (e.g. iron) are essential elements of the modification reaction. The reaction occurs in air, but is

stimulated three-fold by use of 100% oxygen. The reaction will occur slowly in the absence of added transition metals due to the presence of trace quantities of transition metals (1-2  $\mu$ M) in most buffer preparations.

As expected, inhibitors of the modification reaction include anaerobic conditions (e.g.,  $N_2$ ) and metal chelators (e.g. EDTA, citrate, nitrilotriacetate). In addition, the enzymes catalase and superoxide dismutase may inhibit the reaction, consistent with the essential role of reactive oxygen species in the generation of modified T7 DNA polymerase.

As an alternative procedure, it is possible to genetically mutate the T7 gene 5 to specifically inactivate the exonuclease domain of the protein. The T7 gene 5 protein purified from such mutants is ideal for use in DNA sequencing without the need to chemically inactivate the exonuclease by oxidation and without the secondary damage that inevitably occurs to the protein during chemical modification.

Genetically modified T7 DNA polymerase can be isolated by randomly mutagenizing the gene 5 and then screening for those mutants that have lost exonuclease activity, without loss of polymerase activity. Mutagenesis is performed as follows. Single-stranded DNA containing gene 5 (e.g., cloned in pEMBL-8, a plasmid containing an origin for single stranded DNA replication) under the control of a T7 RNA polymerase promoter is prepared by standard procedure, and treated with two different chemical mutagens: hydrazine which will mutate C's and T's, and formic acid, which will mutate G's and A's. Myers et al. 229 Science 242, 1985. The DNA is mutagenized at a dose which results in an average of one base being altered per plasmid molecule. The single-stranded mutagenized plasmids are then primed with a universal 17-mer primer (see above), and used as templates to synthesize the opposite strands. The synthesized strands contain randomly incorporated bases at positions corresponding to the mutated bases in the templates. The double-stranded mutagenized DNA is then used to transform the strain K38/pGP1-2, which is strain K38 containing the plasmid pGP1-2 (Tabor et al., *supra*). Upon heat induction this strain expresses T7 RNA polymerase. The transformed cells are plated at 30°C, with approximately 200 colonies per plate.

Screening for cells having T7 DNA polymerase lacking exonuclease activity is based upon the following finding. The 3' to 5' exonuclease of DNA polymerases serves a proofreading function. When bases are misincorporated, the exonuclease will remove the newly incorporated base which is recognized as "abnormal". This is the case for the analog of dATP, etheno-dATP, which is readily incorporated by T7 DNA polymerase in place of dATP. However, in the presence of the 3' to 5' exonuclease of T7 DNA polymerase, it is excised as rapidly as it is incorporated, resulting in no net DNA synthesis. As shown in figure 6, using the alternating copolymer poly d(AT) as a template, native T7 DNA polymerase catalyzes extensive DNA synthesis only in the presence of dATP, and not etheno-dATP. In contrast, modified T7 DNA polymerase, because of its lack of an associated exonuclease, stably incorporates etheno-dATP into DNA at a rate comparable to dATP. Thus, using poly d(AT) as a template, and dTTP and etheno-dATP as precursors, native T7 DNA polymerase is unable to synthesize DNA from this template, while T7 DNA polymerase which has lost its exonuclease activity will be able to use this template to synthesize DNA.

The procedure for lysing and screening large number of colonies is described in Raetz (72 Proc. Nat. Acad. Sci. 2274, 1975). Briefly, the K38/pGP1-2 cells transformed with the mutagenized gene 5-containing plasmids are transferred from the petri dish, where they are present at approximately 200 colonies per plate, to a piece of filter paper ("replica plating"). The filter paper discs are then placed at 42°C for 60 min to induce the T7 RNA polymerase, which in turn expresses the gene 5 protein. Thioredoxin is constitutively produced from the chromosomal gene. Lysozyme is added to the filter paper to lyse the cells. After a freeze thaw step to ensure cell lysis, the filter paper discs are incubated with poly d(AT), [ $\alpha^{32}$ P]dTTP and etheno-dATP at 37°C for 60 min. The filter paper discs are then washed with acid to remove the unincorporated [ $^{32}$ P]dATP. DNA will precipitate on the filter paper in acid, while nucleotides will be soluble. The washed filter paper is then used to expose X-ray film. Colonies which have induced an active T7 DNA polymerase which is deficient in its exonuclease will have incorporated acid-insoluble  $^{32}$ P, and will be visible by autoradiography. Colonies expressing native T7 DNA polymerase, or expressing a T7 DNA polymerase defective in polymerase activity, will not appear on the autoradiograph.

Colonies which appear positive are recovered from the master petri dish containing the original colonies. Cells containing each potential positive clone will be induced on a larger scale (one liter) and T7 DNA polymerase purified from each preparation to ascertain the levels of exonuclease associated with each mutant. Those low in exonuclease are appropriate for DNA sequencing.

Directed mutagenesis may also be used to isolate genetic mutants in the exonuclease domain of the T7 gene 5 protein. The following is an example of this procedure.

T7 DNA polymerase with reduced exonuclease activity (modified T7 DNA polymerase) can also be distinguished from native T7 DNA polymerase by its ability to synthesize through regions of secondary structure. Thus, with modified DNA polymerase, DNA synthesis from a labeled primer on a template having

secondary structure will result in significantly longer extensions, compared to unmodified or native DNA polymerase. This assay provides a basis for screening for the conversion of small percentages of DNA polymerase molecules to a modified form.

The above assay was used to screen for altered T7 DNA polymerase after treatment with a number of chemical reagents. Three reactions resulted in conversion of the enzyme to a modified form. The first is treatment with iron and a reducing agent, as described above. The other two involve treatment of the enzyme with photooxidizing dyes, Rose Bengal and methylene blue, in the presence of light. The dyes must be titrated carefully, and even under optimum conditions the specificity of inactivation of exonuclease activity over polymerase activity is low, compared to the high specificity of the iron-induced oxidation. Since these dyes are quite specific for modification of histidine residues, this result strongly implicates histidine residues as an essential species in the exonuclease active site.

There are 23 histidine residues in T7 gene 5 protein. Eight of these residues lie in the amino half of the protein, in the region where, based on the homology with the large fragment of *E. coli* DNA polymerase I, the exonuclease domain may be located (Ollis et al. Nature 313, 818, 1984). As described below, seven of the eight histidine residues were mutated individually by synthesis of appropriate oligonucleotides, which were then incorporated into gene 5. These correspond to mutants 1, and 6-10 in table 1.

The mutations were constructed by first cloning the T7 gene 5 from pGP5-3 (Tabor et al., J. Biol. Chem. 262, 1987) into the SmaI and HindIII sites of the vector M13 mp18, to give mGP5-2. (The vector used and the source of gene 5 are not critical in this procedure.) Single-stranded mGP5-2 DNA was prepared from a strain that incorporates deoxyuracil in place of deoxythymidine (Kunkel, Proc. Natl. Acad. Sci. USA 82, 488, 1985). This procedure provides a strong selection for survival of only the synthesized strand (that containing the mutation) when transfected into wild-type *E. coli*, since the strand containing uracil will be preferentially degraded.

Mutant oligonucleotides, 15-20 bases in length, were synthesized by standard procedures. Each oligonucleotide was annealed to the template extended using native T7 DNA polymerase and ligated using T4 DNA ligase. Covalently closed circular molecules were isolated by agarose gel electrophoresis run in the presence of 0.5 µg/ml ethidium bromide. The resulting purified molecules were then used to transform *E. coli* 71.18. DNA from the resulting plaques was isolated and the relevant region sequenced to confirm each mutation.

The following summarizes the oligonucleotides used to generate genetic mutants in the gene 5 exonuclease. The mutations created are underlined. Amino acid and base pair numbers are taken from Dunn et al., 166 J. Molec. Biol. 477, 1983. The relevant wild type sequences of the region of gene 5 mutated are also shown.

Each mutant gene 5 protein was produced by infection of the mutant phage into K38/pGP1-2, as follows. The cells were grown at 30 °C to an  $A_{590} = 1.0$ . The temperature was shifted to 42 °C for 30 min., to induce T7 RNA polymerase. IPTG was added to 0.5 mM, and a lysate of each phage was added at a moi = 10. Infected cells were grown at 37 °C for 90 min. The cells were then harvested and extracts prepared by standard procedures for T7 gene 5 protein.

Extracts were partially purified by passage over a phosphocellulose and DEAE A-50 column, and assayed by measuring the polymerase and exonuclease activities directly, as described above. The results are shown in Table 1.

Table 1  
SUMMARY OF EXONUCLEASE AND POLYMERASE  
ACTIVITIES OF T7 GENE 5 MUTANTS

<u>Mutant</u>	<u>Exonuclease activity, %</u>	<u>Polymerase activity, %</u>
[Wild-type]	[100] <sup>a</sup>	[100] <sup>b</sup>
Mutant 1 (His 123 → Ser 123)	10-25	>90
Mutant 2 (Δ Ser 122, His 123)	0.2-0.4	>90
Mutant 3 (Ser 122, His 123 → Ala 122, Glu 123)	<2	>90

a. Exonuclease activity was measured on single stranded [<sup>3</sup>H]T7 DNA. 100% exonuclease activity corresponds to 5,000 units/mg.

45 b. Polymerase activity was measured using single-stranded calf thymus DNA. 100% polymerase activity corresponds to 8,000 units/mg.

Of the seven histidines tested, only one (His 123: mutant 1) has the enzymatic activities characteristic of modified T7 DNA polymerase. T7 gene 5 protein was purified from this mutant using DEAE-cellulose, phosphocellulose, DEAE-Sephadex and hydroxylapatite chromatography. While the polymerase activity was nearly normal (>90% the level of the native enzyme), the exonuclease activity was reduced 4 to 10-fold.

A variant of this mutant was constructed in which both His 123 and Ser 122 were deleted. The gene 5 protein purified from this mutant has a 200-500 fold lower exonuclease activity, again with retention of 55 >90% of the polymerase activity.

These data strongly suggest that His 123 lies in the active site of the exonuclease domain of T7 gene 5 protein. Furthermore, it is likely that the His 123 is in fact the residue being modified by the oxidation involving iron, oxygen and a reducing agent, since such oxidation has been shown to modify histidine

residues in other proteins (Levine, J. Biol. Chem. 258: 11823, 1983; and Hodgson et al. Biochemistry 14: 5294, 1975). The level of residual exonuclease in mutant 11 is comparable to the levels obtainable by chemical modification.

Although mutations at His residues are described, mutations at nearby sites or even at distant sites may also produce mutant enzymes suitable in this invention, e.g., lys and arg (mutants 4 and 15). Similarly, although mutations in some His residues have little effect on exonuclease activity that does not necessarily indicate that mutations near these residues will not affect exonuclease activity. Mutations which are especially effective include those having deletions of 2 or more amino acids, preferably 6-8, for example, near the His-123 region. Other mutations should reduce exonuclease activity further, or completely.

As an example of the use of these mutant strains the following is illustrative. A pGP5-6 (mutation 11)-containing strain has been deposited with the ATCC (see below). The strain is grown as described above and induced as described in Taber et al. J. Biol. Chem. 262:16212 (1987). K38/pTrx-2 cells may be added to increase the yield of genetically modified T7 DNA polymerase.

The above noted deposited strain also contains plasmid pGP1-2 which expresses T7 RNA polymerase. This plasmid is described in Tabor et al., Proc. Nat. Acad. Sci. USA 82:1074, 1985 and was deposited with the ATCC on March 22, 1985 and assigned the number 40,175.

Referring to Fig. 10, pGP5-6 includes the following segments:

1. EcoRI-SacI-SmaI-BamHI polylinker sequence from M13 mp10 (21bp).
2. T7 bp 14309 to 16747, that contains the T7 gene 5, with the following modifications:  
T7 bp 14703 is changed from an A to a G, creating a SmaI site.  
T7 bp 14304 to 14321 inclusive are deleted (18 bp).
3. SalI-PstI-HindIII polylinker sequence from M13 mp 10 (15 bp)
4. pBR322 bp 29 (HindIII site) to pBR322 bp 375 (BamHI site).
5. T7 bp 22855 to T7 bp 22927, that contains the T7 RNA Polymerase promoter  $\phi$ 10, with BamHI linkers inserted at each end (82 bp).
6. pBR322 bp 375 (BamHI site) to pBR322 bp 4361 (EcoRI site).

#### DNA Sequencing Using Modified T7-type DNA Polymerase

DNA synthesis reactions using modified T7-type DNA polymerase result in chain-terminated fragments of uniform radioactive intensity, throughout the range of several bases to thousands of bases in length. There is virtually no background due to terminations at sites independent of chain terminating agent incorporation (i.e. at pause sites or secondary structure impediments).

Sequencing reactions using modified T7-type DNA polymerase consist of a pulse and chase. By pulse is meant that a short labelled DNA fragment is synthesized; by chase is meant that the short fragment is lengthened until a chain terminating agent is incorporated. The rationale for each step differs from conventional DNA sequencing reactions. In the pulse, the reaction is incubated at 0°C-37°C for 0.5-4 min in the presence of high levels of three nucleotide triphosphates (e.g., dGTP, dCTP and dTTP) and limiting levels of one other labelled, carrier-free, nucleotide triphosphate, e.g., [<sup>35</sup>S] dATP. Under these conditions the modified polymerase is unable to exhibit its processive character, and a population of radioactive fragments will be synthesized ranging in size from a few bases to several hundred bases. The purpose of the pulse is to radioactively label each primer, incorporating maximal radioactivity while using minimal levels of radioactive nucleotides. In this example, two conditions in the pulse reaction (low temperature, e.g., from 0-20°C, and limiting levels of dATP, e.g., from 0.1μM to 1μM) prevent the modified T7-type DNA polymerase from exhibiting its processive character. Other essential environmental components of the mixture will have similar effects, e.g. limiting more than one nucleotide triphosphate or increasing the ionic strength of the reaction. If the primer is already labelled (e.g., by kinasing) no pulse step is required.

In the chase, the reaction is incubated at 45°C for 1-30 min in the presence of high levels (50-500μM) of all four deoxynucleoside triphosphates and limiting levels (1-50μM) of any one of the four chain terminating agents, e.g., dideoxynucleoside triphosphates, such that DNA synthesis is terminated after an average of 50-600 bases. The purpose of the chase is to extend each radioactively labeled primer under conditions of processive DNA synthesis, terminating each extension exclusively at correct sites in four separate reactions using each of the four dideoxynucleoside triphosphates. Two conditions of the chase (high temperature, e.g., from 30-50°C) and high levels (above 50μM) of all four deoxynucleoside triphosphates) allow the modified T7-type DNA polymerase to exhibit its processive character for tens of thousands of bases; thus the same polymerase molecule will synthesize from the primer-template until a dideoxynucleotide is incorporated. At a chase temperature of 45°C synthesis occurs at >700

nucleotides/sec. Thus, for sequencing reactions the chase is complete in less than a second. *ssb* increases processivity, for example, when using dITP, or when using low temperatures or high ionic strength, or low levels of triphosphates throughout the sequencing reaction.

Either [ $\alpha^{35}\text{S}$ ]dATP, [ $\alpha^{32}\text{P}$ ]dATP or fluorescently labelled nucleotides can be used in the DNA sequencing reactions with modified T7-type DNA polymerase. If the fluorescent analog is at the 5' end of the primer, then no pulse step is required.

Two components determine the average extensions of the synthesis reactions. First is the length of time of the pulse reaction. Since the pulse is done in the absence of chain terminating agents, the longer the pulse reaction time, the longer the primer extensions. At 0°C the polymerase extensions average 10 nucleotides/sec. Second is the ratio of deoxyribonucleoside triphosphates to chain terminating agents in the chase reaction. A modified T7-type DNA polymerase does not discriminate against the incorporation of these analogs, thus the average length of extension in the chase is four times the ratio of the deoxynucleoside triphosphate concentration to the chain terminating agent concentration in the chase reaction. Thus, in order to shorten the average size of the extensions, the pulse time is shortened, e.g., to 30 sec. and/or the ratio of chain terminating agent to deoxynucleoside triphosphate concentration is raised in the chase reaction. This can be done either by raising the concentration of the chain terminating agent or lowering the concentration of deoxynucleoside triphosphate. To increase the average length of the extensions, the pulse time is increased, e.g., to 3-4 min; and/or the concentration of chain terminating agent is lowered (e.g., from 20  $\mu\text{M}$  to 2  $\mu\text{M}$ ) in the chase reaction.

#### Example 2: DNA sequencing using modified T7 DNA polymerase

The following is an example of a sequencing protocol using dideoxy nucleotides as terminating agents. 9  $\mu\text{l}$  of single-stranded M13 DNA (mGP1-2, prepared by standard procedures) at 0.7 mM concentration is mixed with 1  $\mu\text{l}$  of complementary sequencing primer (standard universal 17-mer, 0.5 pmole primer /  $\mu\text{l}$ ) and 2.5  $\mu\text{l}$  5X annealing buffer (200 mM Tris-HCl, pH 7.5, 50 mM  $\text{MgCl}_2$ ) heated to 65°C for 3 min, and slow cooled to room temperature over 30 min. In the pulse reaction, 12.5  $\mu\text{l}$  of the above annealed mix was mixed with 1  $\mu\text{l}$  dithiothreitol 0.1 M, 2  $\mu\text{l}$  of 3 dNTPs (dGTP, dCTP, dTTP) 3 mM each (P-L Biochemicals in TE), 2.5  $\mu\text{l}$  [ $\alpha^{35}\text{S}$ ]dATP, (1500 Ci/mmol, New England Nuclear) and 1  $\mu\text{l}$  of modified T7 DNA polymerase described in Example 1 (0.4 mg/ml, 2500 units/ml, i.e. 0.4  $\mu\text{g}$ , 2.5 units) and incubated at 0°C, for 2 min, after vortexing and centrifuging in a microfuge for 1 sec. The time of incubation can vary from 30 sec to 20 min and temperature can vary from 0°C to 37°C. Longer times are used for determining sequences distant from the primer.

4.5  $\mu\text{l}$  aliquots of the above pulse reaction are added to each of four tubes containing the chase mixes, preheated to 45°C. The four tubes, labeled G, A, T, C, each contain trace amounts of either dideoxy (dd) G, A, T, or C (P-L Biochemicals). The specific chase solutions are given below. Each tube contains 1.5  $\mu\text{l}$  dATP 1mM, 0.5  $\mu\text{l}$  5X annealing buffer (200 mM Tris-HCl, pH 7.5, 50mM  $\text{MgCl}_2$ ), and 1.0  $\mu\text{l}$  ddNTP 100  $\mu\text{M}$  (where ddNTP corresponds to ddG,A,T or C in the respective tubes). Each chase reaction is incubated at 45°C (or 30°C-50°C) for 10 min, and then 6  $\mu\text{l}$  of stop solution (90% formamide, 10mM EDTA, 0.1% xylene cyanol) is added to each tube, and the tube placed on ice. The chase times can vary from 1-30 min.

The sequencing reactions are run on standard, 6% polyacrylamide sequencing gel in 7M urea, at 30 Watts for 6 hours. Prior to running on a gel the reactions are heated to 75°C for 2 min. The gel is fixed in 10% acetic acid, 10% methanol, dried on a gel dryer, and exposed to Kodak OM1 high-contrast autoradiography film overnight.

#### Example 3: DNA sequencing using limiting concentrations of dNTPS

In this example DNA sequence analysis of mGP1-2 DNA is performed using limiting levels of all four deoxyribonucleoside triphosphates in the pulse reaction. This method has a number of advantages over the protocol in example 2. First, the pulse reaction runs to completion, whereas in the previous protocol it was necessary to interrupt a time course. As a consequence the reactions are easier to run. Second, with this method it is easier to control the extent of the elongations in the pulse, and so the efficiency of labeling of sequences near the primer (the first 50 bases) is increased approximately 10-fold.

7  $\mu\text{l}$  of 0.75 mM single-stranded M13 DNA (mGP1-2) was mixed with 1  $\mu\text{l}$  of complementary sequencing primer (17-mer, 0.5 pmole primer/ $\mu\text{l}$ ) and 2  $\mu\text{l}$  5X annealing buffer (200 mM Tris-HCl pH 7.5, 50 mM  $\text{MgCl}_2$ , 250 mM NaCl) heated at 65°C for 2 min, and slowly cooled to room temperature over 30 min. In the pulse reaction 10  $\mu\text{l}$  of the above annealed mix was mixed with 1  $\mu\text{l}$  dithiothreitol 0.1 M, 2  $\mu\text{l}$  of 3 dNTPs (dGTP, dCTP, dTTP) 1.5  $\mu\text{M}$  each, 0.5  $\mu\text{l}$  [ $\alpha^{35}\text{S}$ ]dATP, (10  $\mu\text{M}$ ) (about 10  $\mu\text{M}$ , 1500 Ci/mmol, New England

Nuclear) and 2  $\mu$ l modified T7 DNA polymerase (0.1 mg/ml, 1000 units/ml, i.e., 0.2  $\mu$ g, 2 units) and incubated at 37°C for 5 min. (The temperature and time of incubation can be varied from 20°C-45°C and 1-60 min., respectively.)

3.5  $\mu$ l aliquots of the above pulse reaction were added to each of four tubes containing the chase mixes, which were preheated to 37°C. The four tubes, labeled G, A, T, C, each contain trace amounts of either dideoxy G, A, T, C. The specific chase solutions are given below. Each tube contains 0.5  $\mu$ l 5X annealing buffer (200 mM Tris-HCl pH 7.5, 50 mM MgCl<sub>2</sub>, 250 mM NaCl), 1  $\mu$ l 4dNTPs (dGTP, dATP, dTTP, dCTP) 200  $\mu$ M each, and 1.0  $\mu$ l ddNTP 20  $\mu$ M. Each chase reaction is incubated at 37°C for 5 min (or 20°C-45°C and 1-60 min respectively), and then 4  $\mu$ l of a stop solution (95% formamide, 20 mM EDTA, 0.05% xylene-cyanol) added to each tube, and the tube placed on ice prior to running on a standard polyacrylamide sequencing gel as described above.

#### Example 4: Replacement of dGTP with dITP for DNA sequencing

In order to sequence through regions of compression in DNA, i.e., regions having compact secondary structure, it is common to use dITP (Mills et al., 76 Proc. Natl. Acad. Sci. 2232, 1979) or deazaguanosine triphosphate (deaza GTP, Mizusawa et al., 14 Nuc. Acid Res. 1319, 1986). We have found that both analogs function well with T7-type polymerases, especially with dITP in the presence of *ssb*. Preferably these reactions are performed with the above described genetically modified T7 polymerase, or the chase reaction is for 1-2 min., and/or at 20°C to reduce exonuclease degradation.

Modified T7 DNA polymerase efficiently utilizes dITP or deaza-GTP in place of dGTP. dITP is substituted for dGTP in both the pulse and chase mixes at a concentration two to five times that at which dGTP is used. In the ddG chase mix ddGTP is still used (not ddITP).

The chase reactions using dITP are sensitive to the residual low levels (about 0.01 units) of exonuclease activity. To avoid this problem, the chase reaction times should not exceed 5 min when dITP is used. It is recommended that the four dITP reactions be run in conjunction with, rather than to the exclusion of, the four reactions using dGTP. If both dGTP and dITP are routinely used, the number of required mixes can be minimized by: (1) Leaving dGTP and dITP out of the chase mixes, which means that the four chase mixes can be used for both dGTP and dITP chase reactions. (2) Adding a high concentration of dGTP or dITP (2  $\mu$ l at 0.5 mM and 1-2.5 mM respectively) to the appropriate pulse mix. The two pulse mixes then each contain a low concentration of dCTP, dTTP and [ $\alpha^{35}$ S]dATP, and a high concentration of either dGTP or dITP. This modification does not usually adversely effect the quality of the sequencing reactions, and reduces the required number of pulse and chase mixes to run reactions using both dGTP and dITP to six.

The sequencing reaction is as for example 3, except that two of the pulse mixes contain a) 3 dNTP mix for dGTP: 1.5  $\mu$ M dCTP, dTTP, and 1 mM dGTP and b) 3 dNTP mix for dITP: 1.5  $\mu$ M dCTP, dTTP, and 2 mM dITP. In the chase reaction dGTP is removed from the chase mixes (i.e. the chase mixes contain 30  $\mu$ M dATP, dTTP and dCTP, and one of the four dideoxynucleotides at 8  $\mu$ M), and the chase time using dITP does not exceed 5 min.

#### Deposits

Strains K38/pGP5-5/pTrx-2, K38/pTrx-2 and M13 mGP1-2 have been deposited with the ATCC and assigned numbers 67,287, 67,286, and 40,303 respectively. These deposits were made on January 13, 1987. Strain K38/pGP1-2/pGP5-6 was deposited with the ATCC. On December 4, 1987, and assigned the number 67571.

Applicants' and their assignees acknowledge their responsibility to replace these cultures should they die before the end of the term of a patent issued hereon, 5 years after the last request for a culture, or 30 years, whichever is the longer, and its responsibility to notify the depository of the issuance of such a patent, at which time the deposits will be made irrevocably available to the public. Until that time the deposits will be made irrevocably available to the Commissioner of Patents under the terms of 37 CFR Section 1-14 and 35 USC Section 112.

#### Claims

1. A method of producing a purified modified DNA polymerase which method comprises expressing a modified gene which gene encodes a modified processive DNA polymerase which has sufficient DNA polymerase activity for use in DNA sequencing when said polymerase is combined with any cofactor necessary for said DNA polymerase activity and which results from the modification of a naturally

- occurring gene modified in that one or more amino acids in the 3' - 5' exonuclease domain of said naturally occurring DNA polymerase are replaced by an amino acid other than that naturally occurring at the site of substitution or are deleted so as to reduce the activity of naturally occurring 3' - 5' exonuclease activity of the naturally occurring DNA polymerase.
2. A method according to claim 1 characterised in that the polymerase activity of the modified DNA polymerase is at least 90% of that of the naturally occurring DNA polymerase.
  3. A method according to claim 1 or claim 2 further characterised in that said polymerase is a modified bacteriophage T7-type DNA polymerase which has a 3' - 5' exonuclease activity at least 50% lower than the naturally-occurring exonuclease activity of naturally occurring T7-type DNA polymerase.
  4. A method according to any of claims 1 to 3 characterised in that said gene encodes a processive modified DNA polymerase modified to reduce the activity of the naturally occurring 3' - 5' exonuclease activity to less than 500 units per milligram of polymerase.
  5. A method according to any one of claims 1 to 4 further characterised in that said gene has been modified to eliminate the naturally occurring exonuclease activity of the naturally occurring DNA polymerase.
  6. A method according to claim 4 wherein a naturally occurring His residue of the naturally occurring DNA polymerase is replaced or deleted.
  7. A method according to any of claims 4 to 6 characterised in that said processive modified T7-type DNA polymerase is T7 DNA polymerase.
  8. A method according to claim 7 characterised in that His 123 of the naturally occurring T7 DNA polymerase is replaced or deleted.
  9. A method according to claim 7 characterised in that Ser 122 and His 123 are replaced or deleted.
  10. A method according to claim 7 characterised in that amino acid residues Lys 118 to His 123 are deleted.
  11. A method according to claim 7 or claim 9 characterised in that Lys 118 and Arg 119 of the naturally occurring T7 DNA polymerase are replaced or deleted.
  12. A method accord claim 7 characterised in that Arg 131, Lys 136, Lys 140, Lys 144 and Arg 145 of naturally occurring T7 DNA polymerase are replaced or deleted.
  13. A method according to any of claims 1 to 12 wherein the modified processive DNA polymerase is able to remain bound to DNA for at least 500 bases under conditions normally used for DNA sequencing reactions.
  14. A purified modified gene characterised in that it encodes a processive modified T7-type DNA polymerase which polymerase is able to remain bound to DNA for at least 500 bases under conditions normally used for DNA sequencing reactions and which has sufficient DNA polymerase activity for use in DNA sequencing when said polymerase is combined with any host factor necessary for said DNA polymerase activity and which results from the modification of a naturally occurring gene modified to reduce the activity of naturally occurring 3'- 5' exonuclease activity of the naturally occurring DNA polymerase wherein one or more amino acids of the exonuclease domain within the amino terminal half of the T7 DNA polymerase of said naturally occurring DNA polymerase, or the corresponding domain of other T7-type DNA polymerases, are replaced by an amino acid other than that naturally occurring at the site of substitution or are deleted.
  15. A purified modified gene according to claim 14 characterised in that one or more of the amino acids of the exonuclease domain from the amino terminal to amino acid residue 224 of T7 DNA polymerase of said naturally occurring DNA polymerase, or the corresponding domain of other T7-type DNA poly-

merases, are replaced by an amino acid other than that naturally occurring at the site of substitution or are deleted.

- 5 16. A purified modified gene according to claims 14 or 15 characterised in that the polymerase activity of the processive T7-type modified polymerase is at least 90% of that of the naturally occurring T7-type DNA polymerase.
- 10 17. A purified modified gene according to any of claims 14 to 15 further characterised in that said polymerase has an exonuclease activity at least 50% lower than the naturally-occurring exonuclease activity of naturally occurring T7-type DNA polymerase.
- 15 18. A purified modified gene according to any of claims 14 to 17 characterised in that said gene encodes a processive modified DNA polymerase modified to reduce the activity of the naturally occurring exonuclease activity to less than 500 units per milligram of polymerase.
- 20 19. A purified modified gene as claimed in any of claims 14 to 18 further characterised in that said gene has been modified to eliminate the naturally occurring exonuclease activity of the naturally occurring DNA polymerase.
- 25 20. A purified modified gene according to any of claims 14 to 19 further characterised in that a His residue of the 3'- 5' exonuclease domain of the naturally occurring DNA polymerase is replaced or deleted.
- 30 21. A purified modified gene according to any of claims 14 to 20 characterised in that said processive modified T7-type DNA polymerase is T7 DNA polymerase.
- 35 22. A purified modified gene as claimed in claim 21 characterised in that His 123 of the naturally occurring T7 DNA polymerase is replaced or deleted.
- 40 23. A purified modified gene according to claim 21 characterised in that Ser 122 and His 123 are replaced or deleted.
- 45 24. A purified modified gene according to claim 21 characterized in that amino acid residues Lys 118 to His 123 are deleted.
- 50 25. A purified modified gene according to claim 21 characterized in that Lys 118 and Arg 119 of the naturally occurring T7 DNA polymerase are replaced or deleted.
- 55 26. A purified modified gene according to claim 21 characterized in that Arg 131, Lys 136, Lys 140, Lys 144 and Arg 145 of the naturally occurring T7 DNA polymerase are replaced or deleted.
27. The use of a modified processive DNA polymerase produced according to the method of claim 1 for DNA sequencing.

#### Patentansprüche

- 45 1. Verfahren zum Herstellen einer gereinigten, modifizierten DNA-Polymerase, bei dem ein modifiziertes Gen expremiert wird, das für eine modifizierte prozessive DNA-Polymerase codiert, die eine ausreichende DNA-Polymeraseaktivität zur Verwendung beim DNA-Sequenzieren aufweist, wenn die Polymerase mit einem Kofaktor kombiniert wird, der für die DNA-Polymeraseaktivität notwendig ist, und das  
50 durch die Modifikation eines natürlich auftretenden Gens erhalten wird, das dahingehend modifiziert ist, daß eine oder mehrere Aminosäuren in der 3'- 5'-Exonukleasedomäne der natürlich auftretenden DNA-Polymerase entfernt oder durch eine Aminosäure ersetzt ist bzw.sind, die sich von der an der Substitutionsstelle natürlich auftretenden Aminosäure unterscheidet, so daß die natürliche Aktivität der 3'-5'-Exonukleaseaktivität der natürlich auftretenden Polymerase vermindert ist.
- 55 2. Verfahren nach Anspruch 1, dadurch gekennzeichnet, daß die Polymeraseaktivität der modifizierten DNA-Polymerase wenigstens 90% der der natürlich auftretenden DNA-Polymerase ist.

3. Verfahren nach Anspruch 1 oder 2, dadurch gekennzeichnet, daß die Polymerase eine modifizierte DNA-Polymerase von Bakteriophagen vom T7-Typ ist, die eine 3'-5'-Exonukleaseaktivität aufweist, die wenigstens 50% niedriger ist als die natürlich auftretende Exonukleaseaktivität der natürlich auftretenden T7-Typ-DNA-Polymerase.
- 5 4. Verfahren nach einem der Ansprüche 1 bis 3, dadurch gekennzeichnet, daß das Gen für eine prozessive modifizierte DNA-Polymerase codiert, die so modifiziert ist, daß die Aktivität der natürlich auftretenden 3'-5'-Exonukleaseaktivität auf weniger als 500 Einheiten pro Milligramm Polymerase vermindert ist.
- 10 5. Verfahren nach einem der Ansprüche 1 bis 4, dadurch gekennzeichnet, daß das Gen modifiziert ist, um die natürlich auftretende Exonukleaseaktivität der natürlich auftretenden DNA-Polymerase zu eliminieren.
- 15 6. Verfahren nach Anspruch 4, bei dem der natürlich auftretende His-Baustein der natürlich auftretenden DNA-Polymerase ersetzt oder entfernt ist.
- 20 7. Verfahren nach einem der Ansprüche 4 bis 6, dadurch gekennzeichnet, daß die modifizierte T7-Typ-DNA-Polymerase eine T7-Polymerase ist.
8. Verfahren nach Anspruch 7, dadurch gekennzeichnet, daß His 123 der natürlich auftretenden T7-DNA-Polymerase ersetzt oder entfernt ist.
- 25 9. Verfahren nach Anspruch 7, dadurch gekennzeichnet, daß Ser 122 und His 123 ersetzt oder entfernt sind.
10. Verfahren nach Anspruch 7, dadurch gekennzeichnet, daß die Aminosäurebausteine Lys 118 bis His 123 entfernt sind.
- 30 11. Verfahren nach Anspruch 7 oder 9, dadurch gekennzeichnet, daß Lys 118 und Arg 119 der natürlich auftretenden T7-DNA-Polymerase ersetzt oder entfernt sind.
12. Verfahren nach Anspruch 7, dadurch gekennzeichnet, daß Arg 131, Lys 136, Lys 140, Lys 144 und Arg 145 der natürlich auftretenden T7-DNA-Polymerase ersetzt oder entfernt sind.
- 35 13. Verfahren nach einem der Ansprüche 1 bis 12, bei dem die modifizierte prozessive DNA-Polymerase unter Bedingungen, wie sie normalerweise für die DNA-Sequenzierungsreaktionen verwendet werden, in der Lage ist, wenigstens 500 Basen lang an der DNA gebunden zu bleiben.
- 40 14. Gereinigtes modifiziertes Gen, dadurch gekennzeichnet, daß es für eine prozessive modifizierte T7-Typ-DNA-Polymerase codiert, die in der Lage ist, unter Bedingungen, die normalerweise für die DNA-Sequenzierungsreaktionen verwendet werden, wenigstens 500 Basen lang an DNA gebunden zu bleiben, und die zur Verwendung bei der DNA-Sequenzierung eine ausreichende DNA-Polymeraseaktivität aufweist, wenn die Polymerase mit einem Wirtsfaktor zusammengebracht wird, der für die Polymeraseaktivität notwendig ist, und das sich aus der Modifikation eines natürlich auftretenden Gens ergibt, das modifiziert ist, um die Aktivität der natürlich auftretenden 3'-5'-Exonukleaseaktivität der natürlich auftretenden Polymerase zu vermindern, bei der eine oder mehrere Aminosäuren der Exonukleasedomäne innerhalb der aminoterminalen Hälfte der T7-DNA-Polymerase der natürlich auftretenden DNA-Polymerase oder die entsprechende Domäne anderer T7-Typ-DNA-Polymerasen fehlt bzw. fehlen oder durch eine Aminosäure ersetzt ist bzw. sind, die sich von der an der Ersatzstelle natürlicherweise vorhandenen Aminosäure unterscheidet.
- 50 15. Gereinigtes modifiziertes Gen nach Anspruch 14, dadurch gekennzeichnet, daß eine oder mehrere der Aminosäuren der Exonukleasedomäne von dem Aminoende zu dem Aminosäurebaustein 224 der T7-DNA-Polymerase der natürlich auftretenden DNA-Polymerase oder der entsprechenden Domäne anderer T7-Typ-DNA-Polymerasen entfernt oder durch eine Aminosäure ersetzt ist bzw. sind, die sich von der an der Substitutionstelle natürlich auftretenden Aminosäure unterscheidet.
- 55

16. Gereinigtes modifiziertes Gen nach Anspruch 14 oder 15, dadurch gekennzeichnet, daß die Polymeraseaktivität der prozessiven modifizierten T7-Typ-Polymerase wenigstens 90% der natürlich auftretenden T7-Typ-DNA-Polymerase ist.
- 5 17. Gereinigtes modifiziertes Gen nach einem der Ansprüche 14 und 15, dadurch gekennzeichnet, daß die Polymerase eine Exonukleaseaktivität aufweist, die wenigstens 50% kleiner ist als die natürlich auftretende Exonukleaseaktivität der natürlich auftretenden T7-Typ-DNA-Polymerase.
- 10 18. Gereinigtes modifiziertes Gen nach einem der Ansprüche 14 bis 17, dadurch gekennzeichnet, daß das Gen für eine prozessive modifizierte DNA-Polymerase codiert, die modifiziert ist, um die Aktivität der natürlich auftretenden Exonukleaseaktivität auf weniger als 500 Einheiten pro Milligramm Polymerase zu verringern.
- 15 19. Gereinigtes modifiziertes Gen nach einem der Ansprüche 14 bis 18, dadurch gekennzeichnet, daß das Gen modifiziert wurde, um die natürlich auftretende Exonukleaseaktivität zu eliminieren.
- 20 20. Gereinigtes modifiziertes Gen nach einem der Ansprüche 14 bis 19, dadurch gekennzeichnet, daß ein His-Baustein der 3'-5'-Exonukleasedomäne der natürlich auftretenden DNA-Polymerase ersetzt oder entfernt ist.
21. Gereinigtes modifiziertes Gen nach einem der Ansprüche 14 bis 20, dadurch gekennzeichnet, daß die prozessive modifizierte T7-Typ-DNA-Polymerase eine T7-DNA-Polymerase ist.
- 25 22. Gereinigtes modifiziertes Gen nach Anspruch 21, dadurch gekennzeichnet, daß His 123 der natürlich auftretenden T7-DNA-Polymerase ersetzt oder entfernt ist.
23. Gereinigtes modifiziertes Gen nach Anspruch 21, dadurch gekennzeichnet, daß Ser 122 und His 123 ersetzt oder entfernt sind.
- 30 24. Gereinigtes modifiziertes Gen nach Anspruch 21, dadurch gekennzeichnet, daß die Aminosäurebausteine Lys 118 bis His 123 entfernt sind.
25. Gereinigtes modifiziertes Gen nach Anspruch 21, dadurch gekennzeichnet, daß Lys 118 und Arg 119 der natürlich auftretenden T7-DNA-Polymerase ersetzt oder entfernt sind.
- 35 26. Gereinigtes modifiziertes Gen nach Anspruch 21, dadurch gekennzeichnet, daß Arg 131, Lys 136, Lys 140, Lys 144 und Arg 145 der natürlich auftretenden T7-DNA-Polymerase ersetzt oder entfernt sind.
- 40 27. Verwendung einer modifizierten prozessiven DNA-Polymerase, die nach dem Verfahren nach Anspruch 1 hergestellt ist, zum Sequenzieren.

#### Revendications

- 45 1. Procédé de production d'une ADN polymérase modifiée et purifiée, selon lequel on exprime un gène modifié, ce gène codant pour une ADN polymérase progressive modifiée ayant une activité d'ADN polymérase suffisante pour être employée dans un séquençage d'ADN lorsque cette polymérase est associée à tout co-facteur nécessaire à cette activité d'ADN polymérase, celui-ci résultant de la modification d'un gène naturel modifié par remplacement d'un ou plusieurs aminoacides dans le domaine d'exonucléase 3'-5' de cette ADN polymérase naturelle, par un aminoacide autre que celui se trouvant naturellement au site de substitution, ou par délétion de ceux-ci de façon à réduire l'activité d'exonucléase naturelle 3'-5' de l'ADN polymérase naturelle.
- 50 2. Procédé selon la revendication 1, caractérisé en ce que l'activité de polymérase de l'ADN polymérase modifiée, est d'au moins 90 % de celle de l'ADN polymérase naturelle.
- 55 3. Procédé selon la revendication 1 ou 2, caractérisé en outre en ce que la polymérase est une ADN polymérase bactériophagique de type T7 modifiée, ayant une activité d'exonucléase 3'-5', au moins 50 % inférieure à l'activité d'exonucléase naturelle de l'ADN polymérase de type T7 naturelle.

4. Procédé selon l'une quelconque des revendications 1 à 3, caractérisé en ce que le gène code pour une ADN polymérase progressive modifiée de façon à réduire l'activité d'exonucléase naturelle 3'-5', à moins de 500 unités par mg de polymérase.
5. Procédé selon l'une quelconque des revendications 1 à 4, caractérisé en outre en ce que le gène a été modifié de façon à supprimer l'activité d'exonucléase naturelle de l'ADN polymérase naturelle.
6. Procédé selon la revendication 4, dans lequel on remplace ou on supprime un résidu His naturel de l'ADN polymérase naturelle.
7. Procédé selon l'une quelconque des revendications 4 à 6, caractérisé en ce que l'ADN polymérase progressive modifiée de type T7 est une ADN polymérase T7.
8. Procédé selon la revendication 7, caractérisé en ce que le résidu His 123 de l'ADN polymérase T7 naturelle, est remplacé ou supprimé.
9. Procédé selon la revendication 7, caractérisé en ce que les résidus Ser 122 et His 123 sont remplacés ou supprimés.
10. Procédé selon la revendication 7, caractérisé en ce que les résidus dérivés d'acide aminé Lys 118 à His 123, sont supprimés.
11. Procédé selon la revendication 7 ou 9, caractérisé en ce que les résidus Lys 118 et Arg 119 de l'ADN polymérase T7 naturelle, sont remplacés ou supprimés.
12. Procédé selon la revendication 7, caractérisé en ce que les résidus Arg 131, Lys 136, Lys 140, Lys 144 et Arg 145 de l'ADN polymérase T7 naturelle, sont remplacés ou supprimés.
13. Procédé selon l'une quelconque des revendications 1 à 12, dans lequel l'ADN polymérase progressive modifiée, est capable de rester liée à de l'ADN sur au moins 500 bases dans les conditions normalement employées pour des réactions de séquençage de l'ADN.
14. Gène modifié et purifié, caractérisé en ce qu'il code pour une ADN polymérase progressive modifiée de type T7, cette polymérase étant capable de rester liée à de l'ADN sur au moins 500 bases dans les conditions normalement employées pour des réactions de séquençage d'ADN, et ayant une activité d'ADN polymérase suffisante pour une utilisation dans un séquençage d'ADN lorsque cette polymérase est associée à n'importe quel facteur d'hôte nécessaire à cette activité d'ADN polymérase, résultant de la modification d'un gène naturel, modifié de façon à réduire l'activité d'exonucléase naturelle 3'-5' de l'ADN polymérase naturelle, un ou plusieurs acides aminés du domaine d'exonucléase compris dans la moitié amino-terminale de la polymérase, ou dans le domaine correspondant d'autres ADN polymérases de type T7, étant remplacés par un acide aminé autre que celui naturellement présent au site de substitution, ou ceux-ci étant supprimés.
15. Gène modifié et purifié selon la revendication 14, caractérisé en ce qu'un ou plusieurs des acides aminés du domaine d'exonucléase allant de l'extrémité amino-terminale jusqu'au résidu dérivé d'acide aminé 224 de l'ADN polymérase T7 naturelle, ou du domaine correspondant d'autres ADN polymérases de type T7 sont remplacés par un acide aminé autre que celui naturellement présent dans le site de substitution, ou ils sont supprimés.
16. Gène modifié et purifié selon la revendication 14 ou 15, caractérisé en ce que l'activité de polymérase de la polymérase progressive modifiée de type T7 est d'au moins 90 % celle de l'ADN polymérase naturelle de type T7.
17. Gène modifié et purifié selon la revendication 14 ou 15, caractérisé en ce qu'en outre la polymérase a une activité exonucléase, au moins 50 % inférieure à l'activité d'exonucléase naturelle de l'ADN polymérase naturelle de type T7.

18. Gène modifié et purifié selon l'une quelconque des revendications 14 à 17, caractérisé en ce que le gène code pour une ADN polymérase progressive et modifiée de façon à réduire l'activité d'exonucléase naturelle, à moins de 500 unités par mg de polymérase.
- 5 19. Gène modifié et purifié selon l'une quelconque des revendications 14 à 18, caractérisé en outre en ce que ce gène a été modifié de façon à supprimer l'activité d'exonucléase naturelle de l'ADN polymérase naturelle.
- 10 20. Gène modifié et purifié selon l'une quelconque des revendications 14 à 19, caractérisé en outre en ce qu'un résidu His du domaine d'exonucléase 3-5' de l'ADN polymérase naturelle, est remplacé ou supprimé.
- 15 21. Gène modifié ou purifié selon l'une quelconque des revendications 14 à 20, caractérisé en ce que cette ADN polymérase progressive modifiée de type T7 est une ADN polymérase de type T7.
22. Gène modifié et purifié selon la revendication 21, caractérisé en ce que le résidu His 123 de l'ADN polymérase T7 naturelle est remplacé ou supprimé.
- 20 23. Gène modifié et purifié selon la revendication 21, caractérisé en ce que les résidus Ser 122 et His 123 sont remplacés ou supprimés.
24. Gène modifié et purifié selon la revendication 21, caractérisé en ce que les résidus dérivés d'acide Lys 118 à His 123 sont supprimés.
- 25 25. Gène modifié et purifié selon la revendication 21, caractérisé en ce que les résidus Lys 118 et Arg 119 de l'ADN polymérase T7 naturelle sont remplacés ou supprimés.
26. Gène modifié et purifié selon la revendication 21, caractérisé en ce que les résidus Arg 131, Lys 136, Lys 140, Lys 144 et Arg 145 de l'ADN polymérase T7 naturelle, sont remplacés ou supprimés.
- 30 27. Utilisation d'une ADN polymérase progressive modifiée, produite selon le procédé de la revendication 1, pour le séquençage d'ADN.
